

Fork accrual after adopting a sustainability practice, against matched never-adopting controls

- mean DiD, pre-event trend flat
- mean DiD, pre-event gap already rising
- ◆ jump at adoption, net of the pre-event trend

Practices are ordered by how much of the variance in the JOSS score their criterion accounts for, since JOSS compliance is the strongest predictor of adoption and is a composite rather than a dated act. Neither the license nor citability is one of the five JOSS criteria, though a license is a submission requirement. Bars are 95% intervals from 2,000 cluster bootstrap resamples of treated repositories. Median is the per-repository median DiD and % up the share whose DiD exceeds zero; both are unaffected by a single large project, unlike the mean. p is a Wilcoxon signed-rank test on the per-repository DiD. A rising pre-event trend means the treated repositories were already pulling ahead before adopting, so their mean DiD absorbs part of that trajectory and the jump is the defensible estimate. Mean from top repo is the share of the mean contributed by its single largest repository.
